- Steiner Forest CS-Mechanism

## The ingredients:

- A service provider.
- A set  $U$  of potential users (agents, customers).
- Each user  $j \in U$  has a (private) utility  $u_j$  (the price  $j$  is willing to pay to receive the service).
- A cost-function  $c: c(Q)$  is the cost for servicing a set  $Q \subseteq U$ .  $c(Q)$  is usually given by the solution to an optimization problem.

## The ingredients:

- A service provider.
- A set  $U$  of potential users (agents, customers).
- Each user  $j \in U$  has a (private) utility  $u_j$  (the price  $j$  is willing to pay to receive the service).
- A cost-function  $c: c(Q)$  is the cost for servicing a set  $Q \subseteq U$ .  $c(Q)$  is usually given by the solution to an optimization problem.

## Cost-Sharing Mechanism:

- Receive bids  $b_j$  from all users  $j \in U$ .
- Select recipients  $Q \subseteq U$  using bids.
- Distribute service cost  $c(Q)$  among users in  $Q$ : Determine payment  $p_j$  for each  $j \in Q$ .

## Shapley cost shares

- Select a subset  $Q$  and a tree  $T$  spanning  $Q$
- Share the cost of every edge of  $T$  evenly between the players served by the edge
- All players in  $Q$  should bid more than the individual cost-share

■ **Benefit** of user  $j$  is  $u_j - p_j$  if  $j \in Q$ , and 0 otherwise.

■ **Users may lie about their utilities to increase benefit.**

## Objectives:

■ **Strategyproofness:** Dominant strategy for each user is to bid true utility.

■ **Group-Strategyproofness:** Same holds even if users collaborate. No side payments between users.

■ **Cost Recovery or Budget Balance:**  $\sum_{j \in Q} p_j \geq c(Q)$ .

■ **Competitiveness:**  $\sum_{j \in Q} p_j \leq \text{opt}_Q$ .

## Input:

- undirected graph  $G = (V, E)$
- non-negative edge costs  $c : E \rightarrow \mathbb{R}^+$
- set of **facilities**  $F \subseteq V$
- facility  $i$  has facility opening cost  $f_i$
- set of **demand points**  $D \subseteq V$
- $c_{ij}$ : cost of connecting demand point  $j$  to facility  $i$ .  
Connection cost satisfy triangle inequality

## Goal: Compute

- set  $F' \subseteq F$  of opened facilities; and
- function  $\phi : \mathcal{D} \rightarrow \mathcal{F}'$  assigning demand points to opened facilities that minimizes

$$\sum_{i \in F'} f_i + \sum_{j \in \mathcal{D}} c_{\phi(j)j}$$

### Steiner Forests

### Steiner Forest CS-Mechanism

At time 0, set all  $\alpha_j = 0$  and  $\beta_{ij} = 0$  and declare all demands unconnected.

While there is an unconnected demand:

- Raise uniformly all  $\alpha_j$ 's of unconnected demands
  - If  $\alpha_j = c_{ij}$ , declare demand  $j$  **tight** with facility  $i$
  - For a tight constraint  $ij$ , raise both  $\alpha_j$  and  $\beta_{ij}$
  - If  $\sum_j \beta_{ij} = f_i$  at time  $t_i$ , declare:
    - ◆ Facility  $i$  *temporarily opened* at time  $t_i$ ;
    - ◆ All unconnected demands  $j$  that are tight with  $i$  *connected*;
- [Jain and Vazirani, 1999][Mettu and Plaxton, 2000]

## Opening facilities:

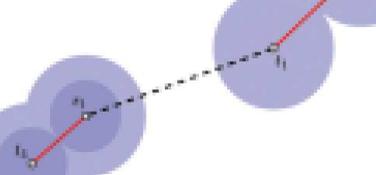

Demand points contribute to more permanently opened facilities. Not enough money for all of them.

- Facility  $i$  temporarily opened at time  $t_i$ ;
- Declare facility  $i$  permanently opened if there is no permanently opened facility within distance  $2t_i$ .

Open all permanently opened facilities.

Connect each demand to the nearest opened facility.

## Demands connected to opened facilities

- $\alpha_j = c_{ij} + \beta_{ij}$  for demands connected to opened facility  $i$ .
- $\alpha_j$  pays for connection cost  $c_{ij}$  and contribute with  $\beta_{ij}$  to  $f_i$ .
- Since other opened facilities are at distance  $> t_i$ ,  $\alpha_j$  does not pay for opening any other facility.

## Demands connected to temporarily opened facilities

- Demand  $j$  connected to temporarily opened facility  $i$ . There exists an opened facility  $i'$  with  $c_{ii'} \leq 2t_i$ .
- Since  $c_{ji} \leq \alpha_j$  and  $t_i \leq \alpha_j$ ,  $c_{ji'} \leq c_{ji} + c_{ii'} \leq 3\alpha_j$

- If some city's cost share goes beyond its bid, then discard the city from all further considerations.
- If for some closed facility  $i$ , the total offer it gets is equal to the opening cost, then the facility  $i$  is opened, and every city  $j$  that has a non-zero offer to  $i$  is connected to  $i$ .
- If some unconnected city  $j$ 's cost share is equal to its connection cost to an already opened facility  $i$ , then connect city  $j$  to facility  $i$ .

### Steiner Forest CS-Mechanism

Truthfulness follows from bid independence:

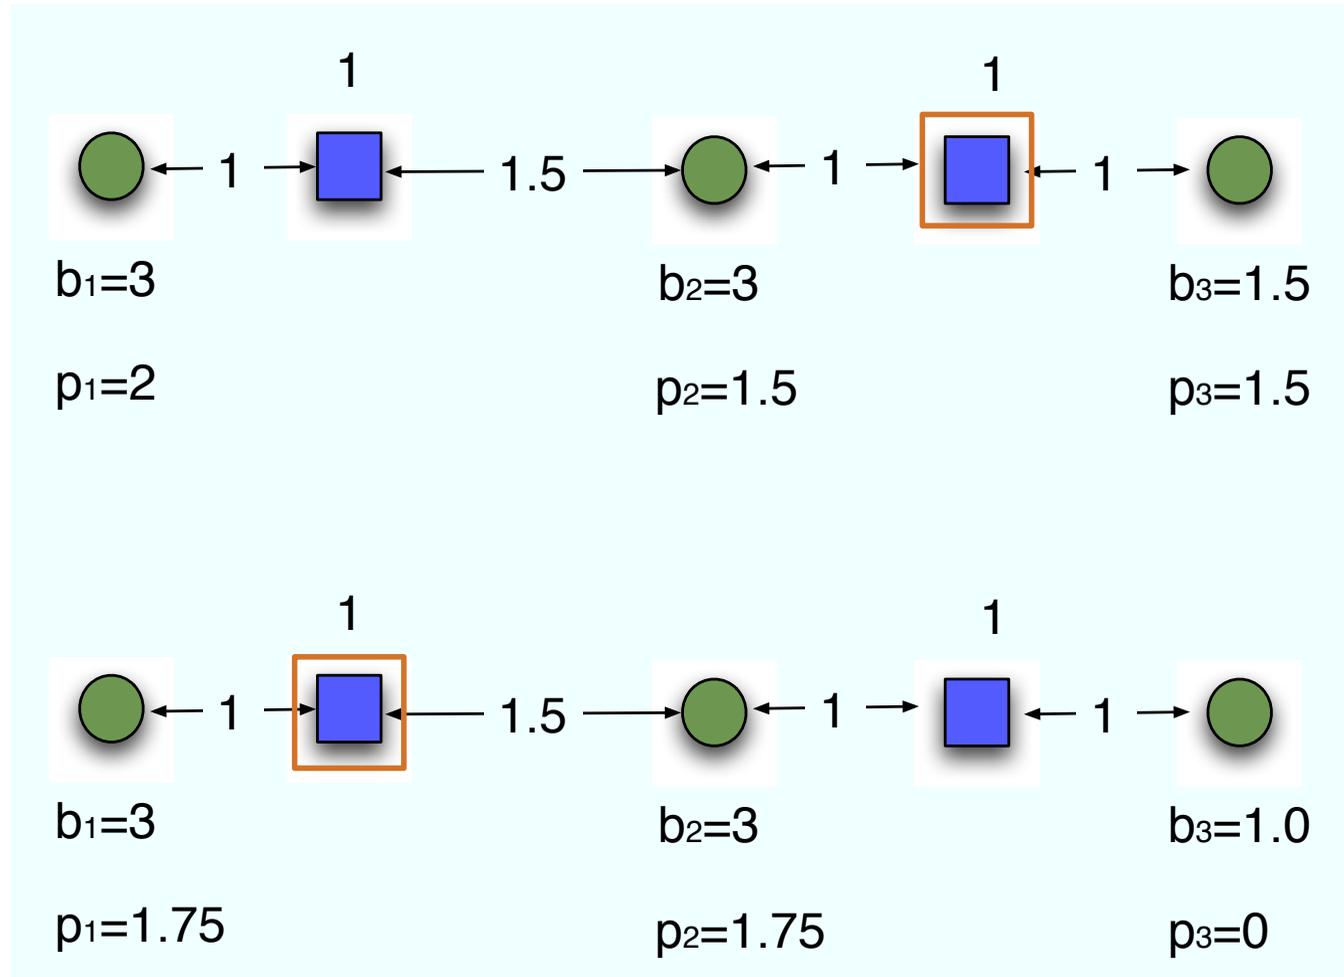

- Lowering the bid might result in early discard:  $\text{payoff}=0$
- Raising the bid might result in paying more than the bid:  $\text{payoff}<0$

Primal dual algorithms that monotonically increase dual variables often result in truthful cost-sharing mechanism.

Excercise: Derive a truthful mechanism for set cover.

### Steiner Forests

### Steiner Forest CS-Mechanism

- Needs a more equitable notion of cost-sharing
- Intuitively, The cost share of all other players should increase if one player leaves the game
- This would prevent coalitions to manipulate the game by pushing some of the members out of the game
- Observe that the only players of the coalitions that will misreport utilities are those with 0 payoff!
- We do not allow side payments, i.e., transfer utility between members of the coalition

### Steiner Forest CS-Mechanism

Moulin–Shenker mechanism: Use cross-monotonic cost-sharing method to obtain group-strategyproof mechanisms.

## Moulin–Shenker Mechanism:

1. Initialize:  $Q \leftarrow U$ .
2. If for each user  $j \in Q$ :  $\xi_Q(j) \leq b_j$  then stop.
3. Otherwise, remove from  $Q$  all users with  $\xi_Q(j) > b_j$  and repeat.

# Moulin–Shenker Mechanism

Designing a cost-sharing mechanism that is **group-strategyproof**, satisfies **competitiveness** and **(approximate) budget balance**.

⇓ reduces to

Designing a **cross-monotonic** cost-sharing method  $\xi$  that satisfies **competitiveness** and **(approximate) budget balance**.

#### Lower Bounds

- In traditional Primal Dual algorithms, if a new city is added, the cost share of nearby cities is decreased, while farther cities can be negatively affected
- A ghost process uniformly raises every dual variable  $\alpha_j$  even after user  $j$  is connected, to contribute to open other facilities
- The cost share of user  $j$  is still the earliest time of connection of user  $j$
- How can we limit the number and the cost of opened facilities?
- How can we recover at least a constant fraction of the opening cost?

[Pal and Tardos, 2003]

- Cost-shares

- Example of execution of the algorithm

- Opening facilities

- Cost recovery I

- Cost recovery II

- Steiner Forests

- Steiner Forest CS-Mechanism

- Lifted-Cut Dual Relaxation

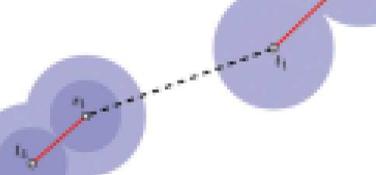

- Lower Bounds

- $t(i)$ : when facility  $i$  becomes full
- $S_i$ : users contributing to making facility  $i$  full, all within distance  $t(i)$  from  $i$
- Raise cost share  $\alpha_j$  till a facility that is touched becomes full or  $j$  touches a full facility:

$$\xi_j = \min\{\min_{i:j \in S_i} t(i), \min_{i:j \notin S_i} c_{ij}\}$$

- Cost shares are cross-monotonic since by adding more users, every facility becomes full earlier
- **Attention! Not all full facilities are opened**

- Cost recovery I
- Cost recovery II

- Steiner Forests

- Steiner Forest CS-Mechanism

- Lifted-Cut Dual Relaxation

- Lower Bounds

- Open a full facility  $i$  if there is no open facility  $i'$  at distance  $c_{ii'} \leq 2t(i)$

- Assign every city to the closest open facility  $i$

**Lemma:** For every two open facilities  $i, i'$ ,  $S_i \cap S_{i'} = \emptyset$ .

Proof: Assume  $i$  to open after  $i'$ . If there is a point in  $S_i \cup S_{i'}$  then  $c_{ii'} \leq 2t(i)$ .

To prove:

- If  $j \in S_i$ ,  $\xi_j$  pays at least for  $t(i)/3$
- If  $j \notin S_i$   $\xi_j$  pays 1/3 of the connection cost to the closest open facility

# Cost recovery I

Steiner Forests

Steiner Forest CS-Mechanism

Lifted-Cut Dual Relaxation

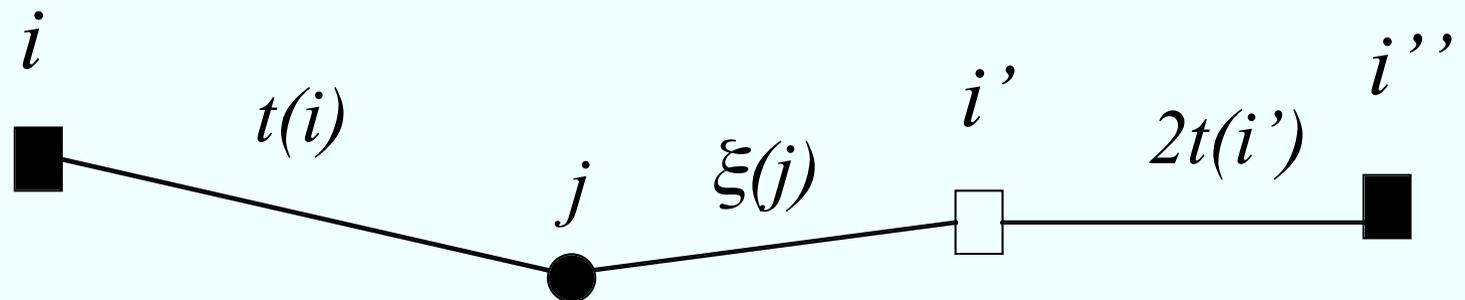

Lower Bounds

**Lemma:** For every  $j \in S_i$ ,  $\xi_j \geq t(i)/3$ .

Proof:

- If  $\xi_j$  determined by  $i$ , then  $\xi_j = t(i)$  (i.e. 1st full facility touched).
- If determined by facility  $i'$  and  $i'$  is open we get a contradiction since  $c_{ii'} \leq 2t(i)$ .
- Otherwise, assume  $\xi_j < t(i)/3$  and  $i'$  not open. We have a facility  $i''$  such that  $c_{i'i''} \leq 2t(i') \leq 2\xi_j$ . A contradiction since

$$c_{ii''} \leq c_{ij} + c_{ji'} + c_{i'i''} \leq t(i) + \xi_j + 2\xi_j \leq 2t(i)$$

# Cost recovery II

- Lifted-Cut Dual Relaxation

- Lower Bounds

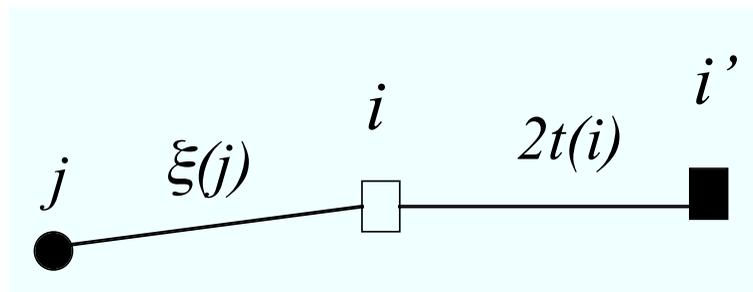

**Lemma:** Assume for every open facility  $i$ ,  $j \notin S_i$ . If  $j$  has been allocated to open facility  $i$  then  $\xi_j \geq c_{ji}/3$ .

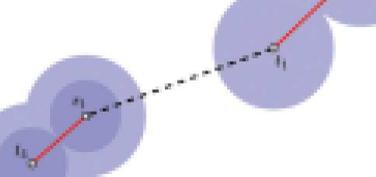

Proof:

Assume  $i$  is the first facility that  $j$  touches.

- If  $i$  is open then  $\xi_j = c_{ji}$ .
- If  $i$  not open, there exists  $i'$  such that  $c_{ii'} \leq 2t(i)$  to which  $j$  is allocated. It follows:

$$c_{ji'} \leq c_{ji} + c_{ii'} \leq \xi_j + 2t(i) \leq 3\xi_j$$

Steiner Forest CS-Mechanism

Lifted-Cut Dual Relaxation

Lower Bounds

**Theorem [Agrawal, Klein, Ravi '95]:** Algorithm computes forest  $F$  and dual  $y$  such that

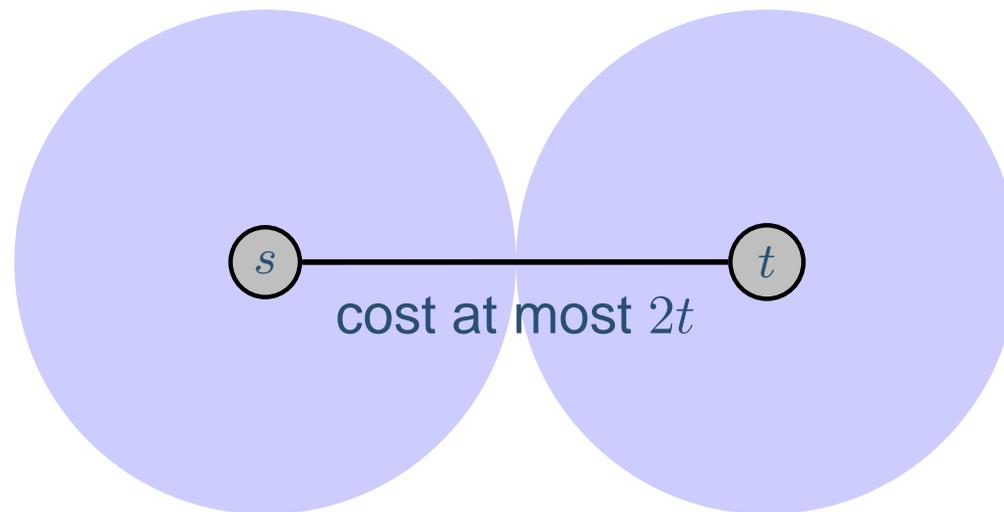

$$c(F) \leq (2 - 1/k) \cdot \sum_U y_U \leq (2 - 1/k) \cdot \text{opt}_R.$$

# PD-Algorithm: Properties

**Theorem [Agrawal, Klein, Ravi '95]:** Algorithm computes forest  $F$  and dual  $y$  such that

$$c(F) \leq (2 - 1/k) \cdot \sum_U y_U \leq (2 - 1/k) \cdot \text{opt}_R.$$

**Main trick:** Edge  $(s, t)$  becomes tight at time  $t$ .

Use twice the dual around  $s$  and  $t$  to pay for cost of path.

# Lower Bound for Steiner Trees

- $\mathcal{B} := \{\{a_1, \dots, a_k\} : a_i \in A_i, i = 1, \dots, k\}$ .
- For each  $B \in \mathcal{B}$ : vertex  $f_B$  with distance 1 to all vertices in  $B$ .
- $f_B$  is connected to the root  $r$ , with edges of length 3.
- $f_B$  has distance 3 to vertices not in  $B$ .
- For each  $c_l, l = 1, \dots, m$ ,  $c(\{a_1, \dots, a_{i-1}, c_l, a_{i+1}, a_k\}) = k + 3$  implies  $\xi(c_l) = \frac{k+3}{k}$
- Total cost share:

$$\sum_{c \in A_i} \xi(c) + \sum_{j \neq i} \xi(a_j) \leq m \times \frac{k+3}{k} + k + 2$$

- $\text{opt} \geq 2m + k + 3$

## Objectives:

- **Strategyproofness:** Dominant strategy for each user is to bid true utility.
- **Group-Strategyproofness:** Same holds even if users collaborate. No side payments between users.
- **Cost Recovery or Budget Balance:**  $\sum_{j \in Q} p_j \geq c(Q)$ .
- **Competitiveness:**  $\sum_{j \in Q} p_j \leq \text{opt}_Q$ .
- **$\alpha$ -Efficiency approximate maximum social welfare:**

$$u(Q) - c(Q) \geq \frac{1}{\alpha} \cdot \max_{S \subseteq U} [u(S) - C(S)], \quad \alpha \geq 1$$

No mechanism can achieve (approximate) budget balance, truthfulness and efficiency [Feigenbaum et al. '01]

- Summary

- Open Issues

1.  $\beta$ -budget balance: **approximate total cost**

$$\frac{1}{\beta}c(Q) \leq p(Q) \leq \text{opt}_Q, \quad \beta \geq 1$$

2. Group-strategyproofness: **bidding truthfully**  $b_i = u_i$  is a dominant strategy for every user  $i \in U$ , even if users cooperate

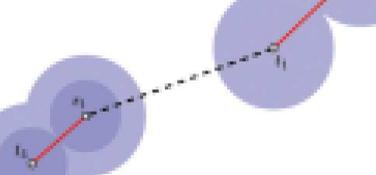

3.  $\alpha$ -approximate: **approximate minimum social cost**

$$\Pi(Q) \leq \alpha \cdot \min_{S \subseteq U} \Pi(S), \quad \alpha \geq 1$$

where  $\Pi(S) := u(U \setminus S) + C(S)$

- Objectives
- Known Results - Social Cost
- Summary
- Open Issues

- Introduced cost-sharing mechanisms for network design problems
- Presented a group-strategyproof mechanism for Steiner forests that is 2-budget balance.
- Presented a new undirected cut relaxation for Steiner forests, strictly stronger than the classical undirected cut relaxation.
- Presented a lower bound of 2 on the budget balance approximation of cross-monotonic algorithms for Steiner trees.
