

Building Cellular Models with Light Microscopy

Gene Myers, Director
MPI for Molecular Cell Biology & Genetics
Dresden, DE

Why BioImage Analysis?

- A very significant outcome of the genome projects is that they permit us, using recombinant genetics, to label any genomic entity of interest.

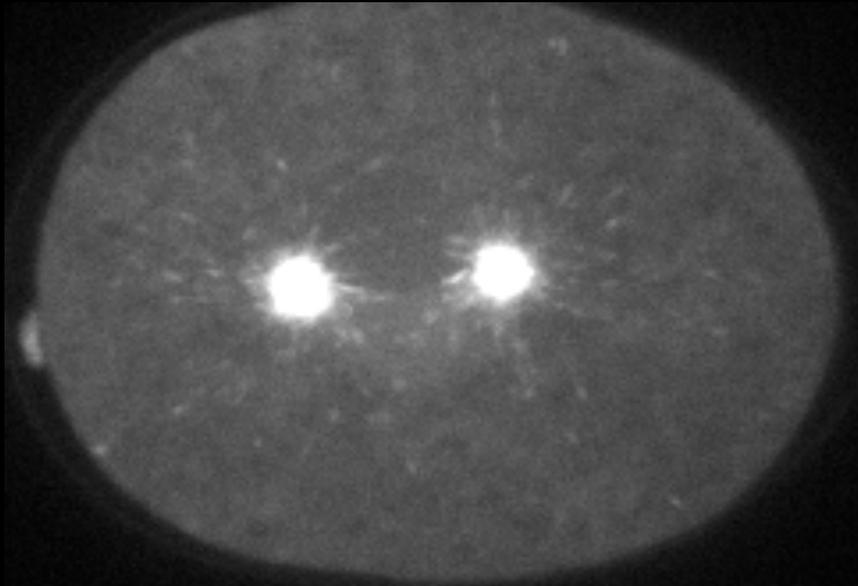

- And we can observe these with current microscopes, to understand function, location, force, signaling, ..
- Interpreting the seas of imagery so produced is computationally hard and increasingly more urgent.

Layered Inference

- Most heuristics can be tuned to report what is (almost) certainly false and what is (almost) certainly true.

- Using a series of such heuristics, repeatedly enlarge what is true and/or eliminate more of what is false
- Can base inferences on the knowledge within the current state

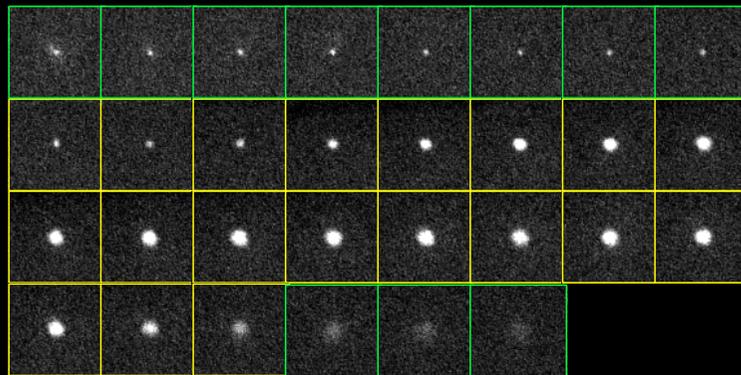

Tracking Centrosomes

Overdetected spots

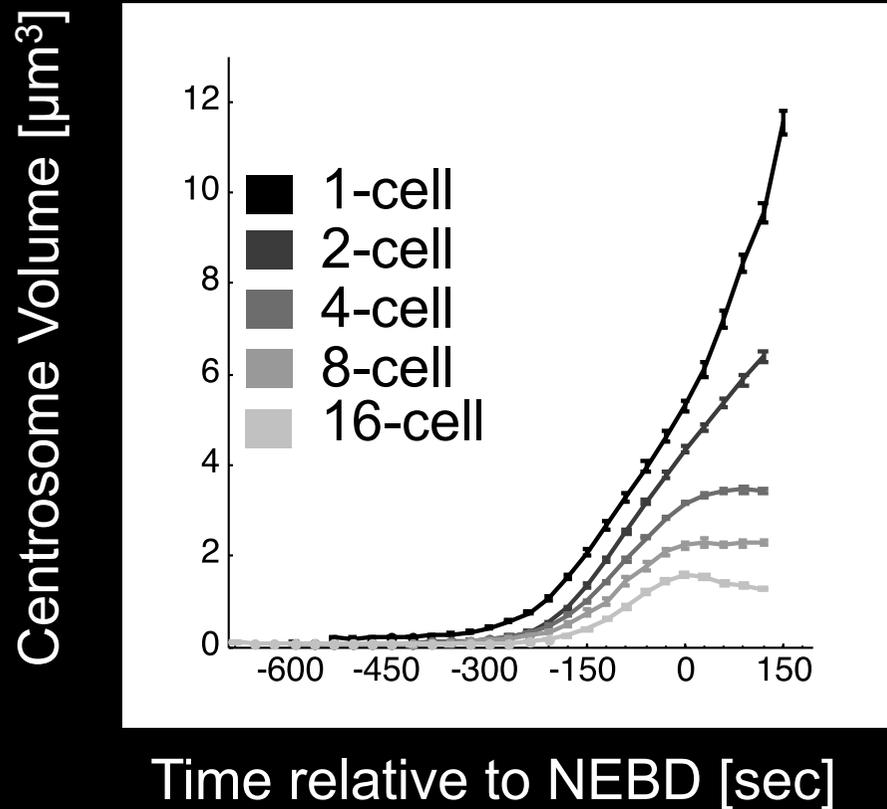

- * Find core subtracks you are sure of (spatial track = appearance track)
- * Learn statistics of true deltas
- * Extrapolate using learned statistics

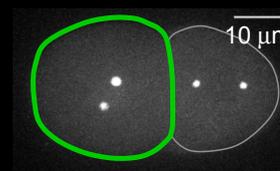

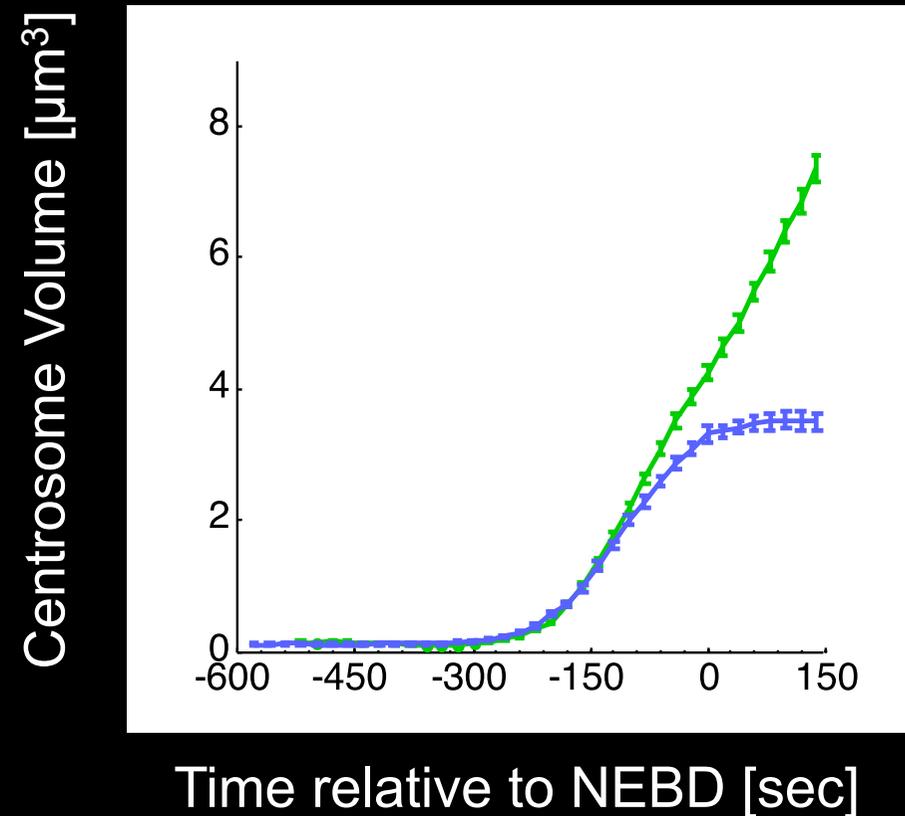

Centrosome Size over Time

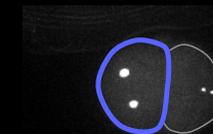

Centrosome Size through Development

Centrosome Size in Smaller AB Cells

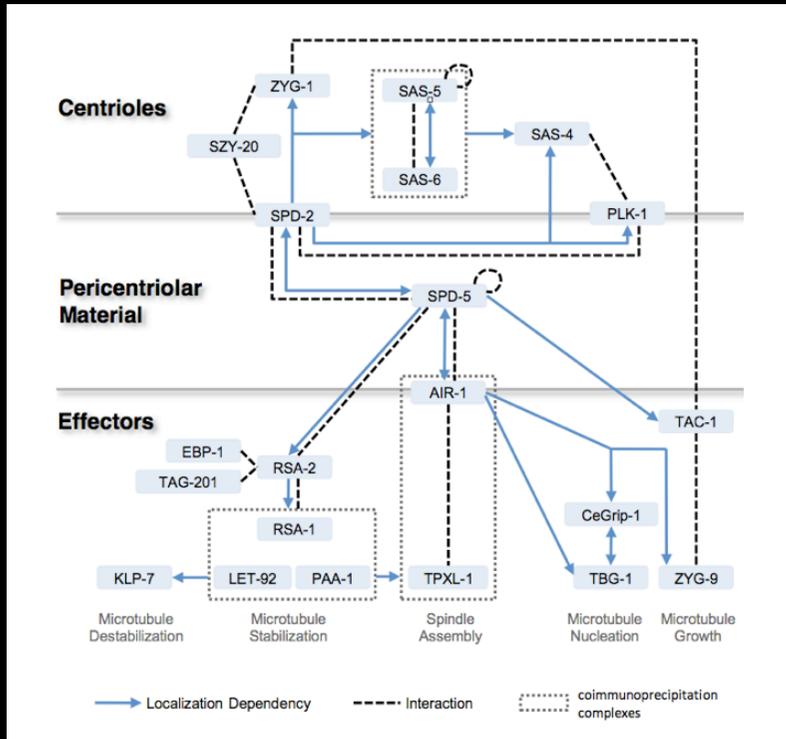

Wild-Type

ani-2(RNAi)

What sets the size of a centrosome?

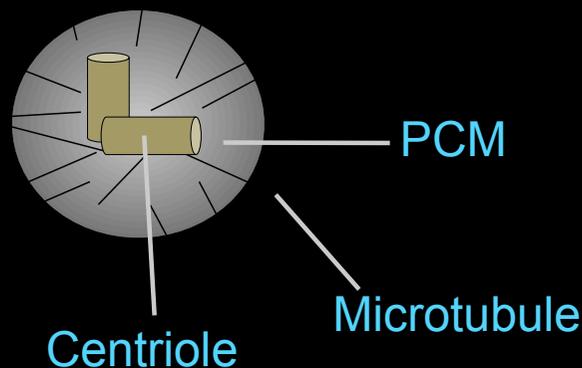

Limiting Component Hypothesis:

The available amount of one or more centrosome components in the cytoplasm determines centrosome size.

153 conditions
1409 embryos
5.5M images

- Size proportional to cell volume
- Size independent of cell type
- Volume independent of # of centrosomes
- Turning off transcription induces no change
- *spd-2*, *spd-5*, *air-1* all needed
- up/down expression:

air-1 no, *spd-2* yes, *spd-5* no

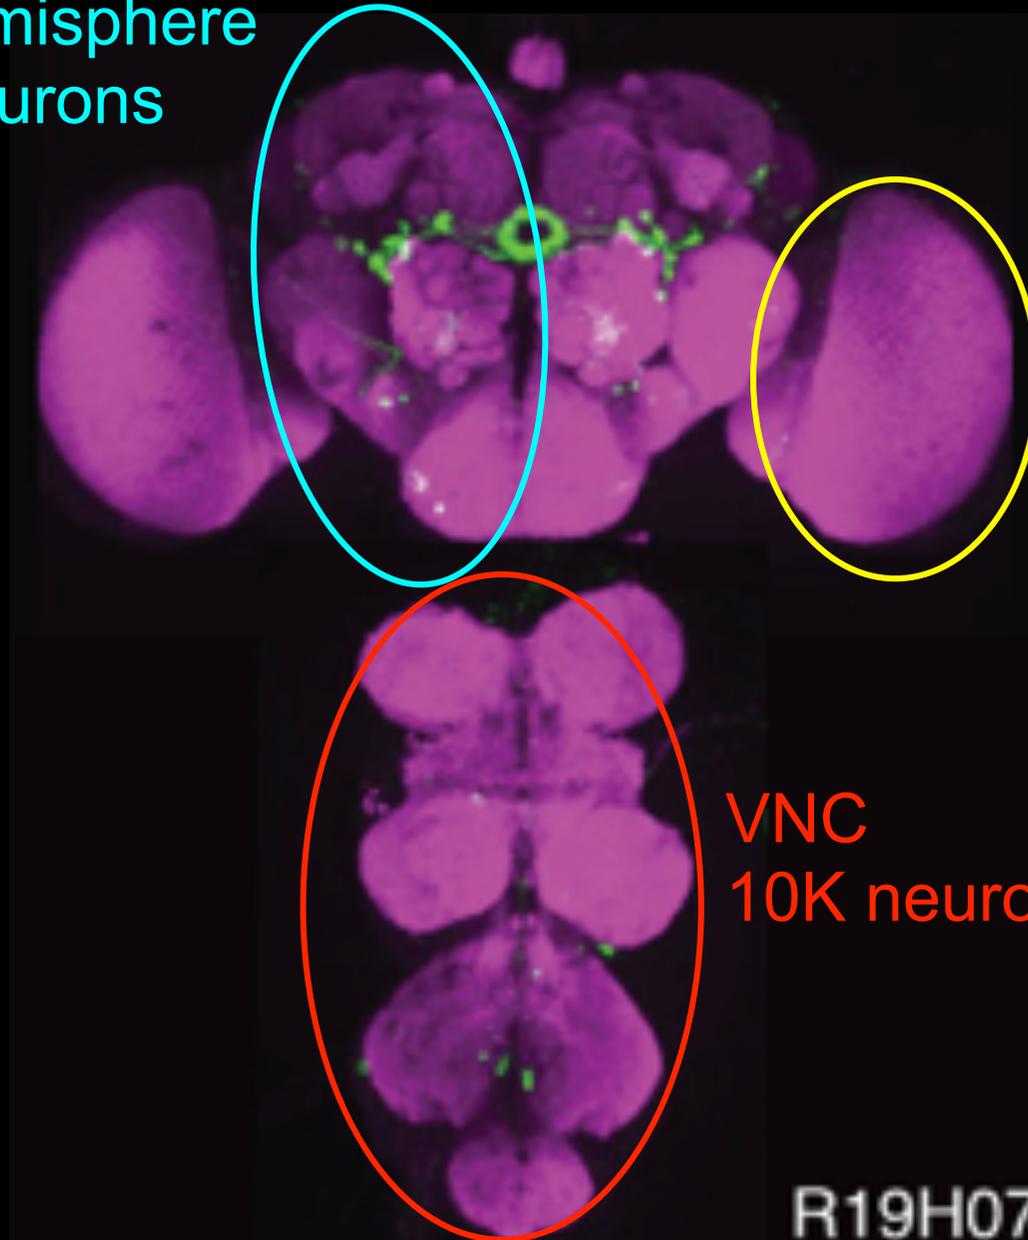

*Currents Biology*¹⁰21 (2011)

The Structure Of A Fly's Brain I

Core Hemisphere
20K neurons

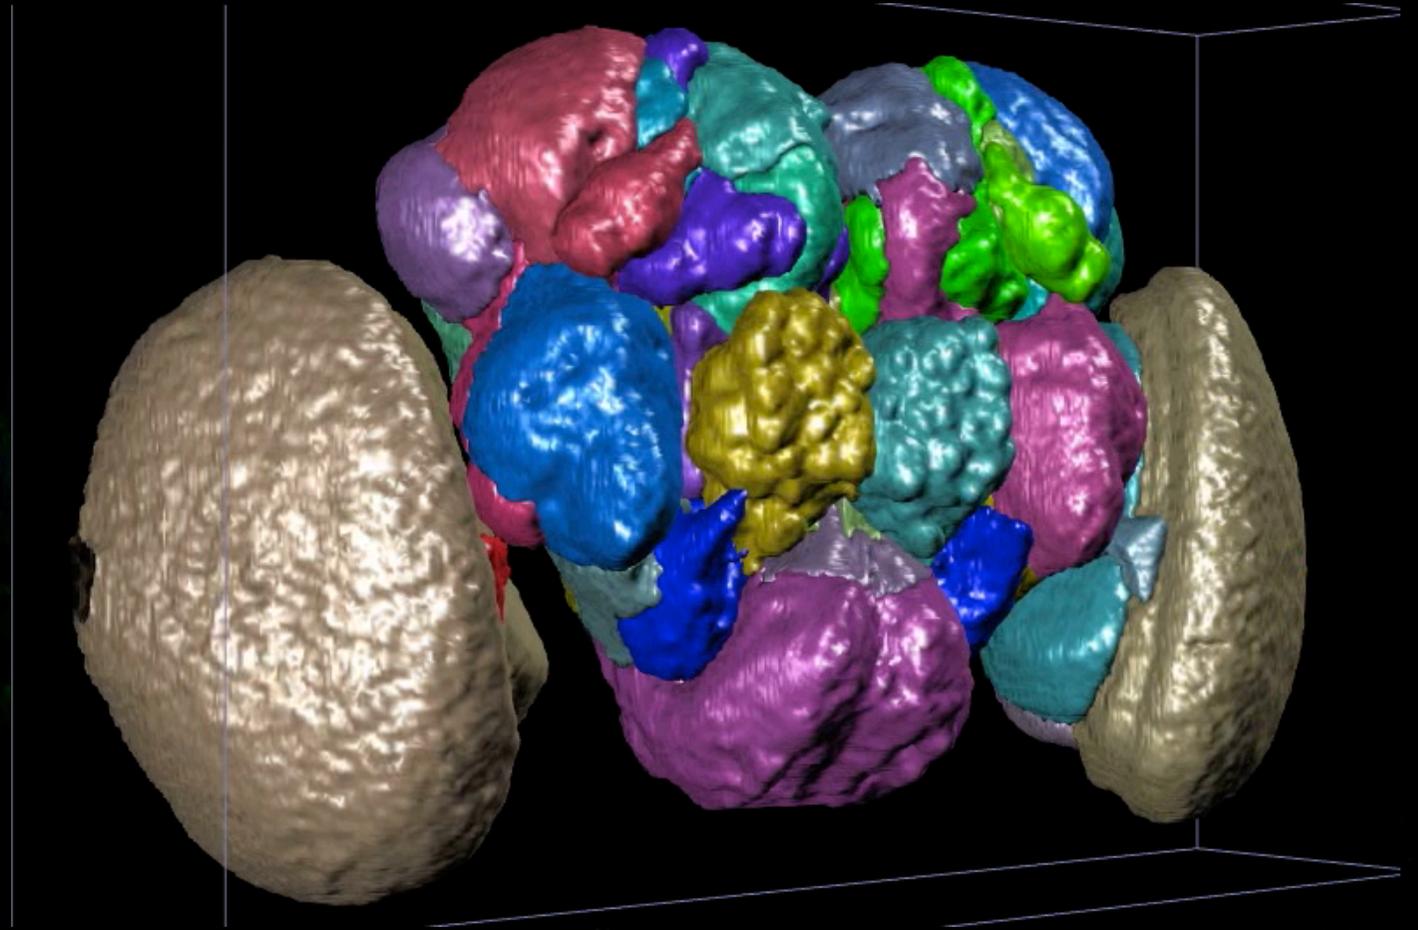

Optic Lobe
30K neurons

VNC
10K neurons

Structure Of A Fly's Brain II

Vaa3D: w. H. Peng

A hemisphere =
~50 glia-isolated compartments

Structure Of A Fly's Brain III

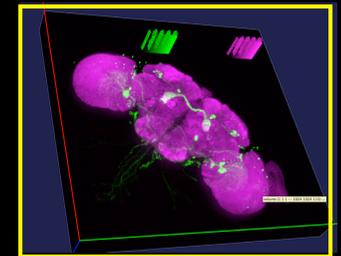

Anatomy of a Fly Brain *with Light*

What we now know about image analysis for adult fly brain imaging:

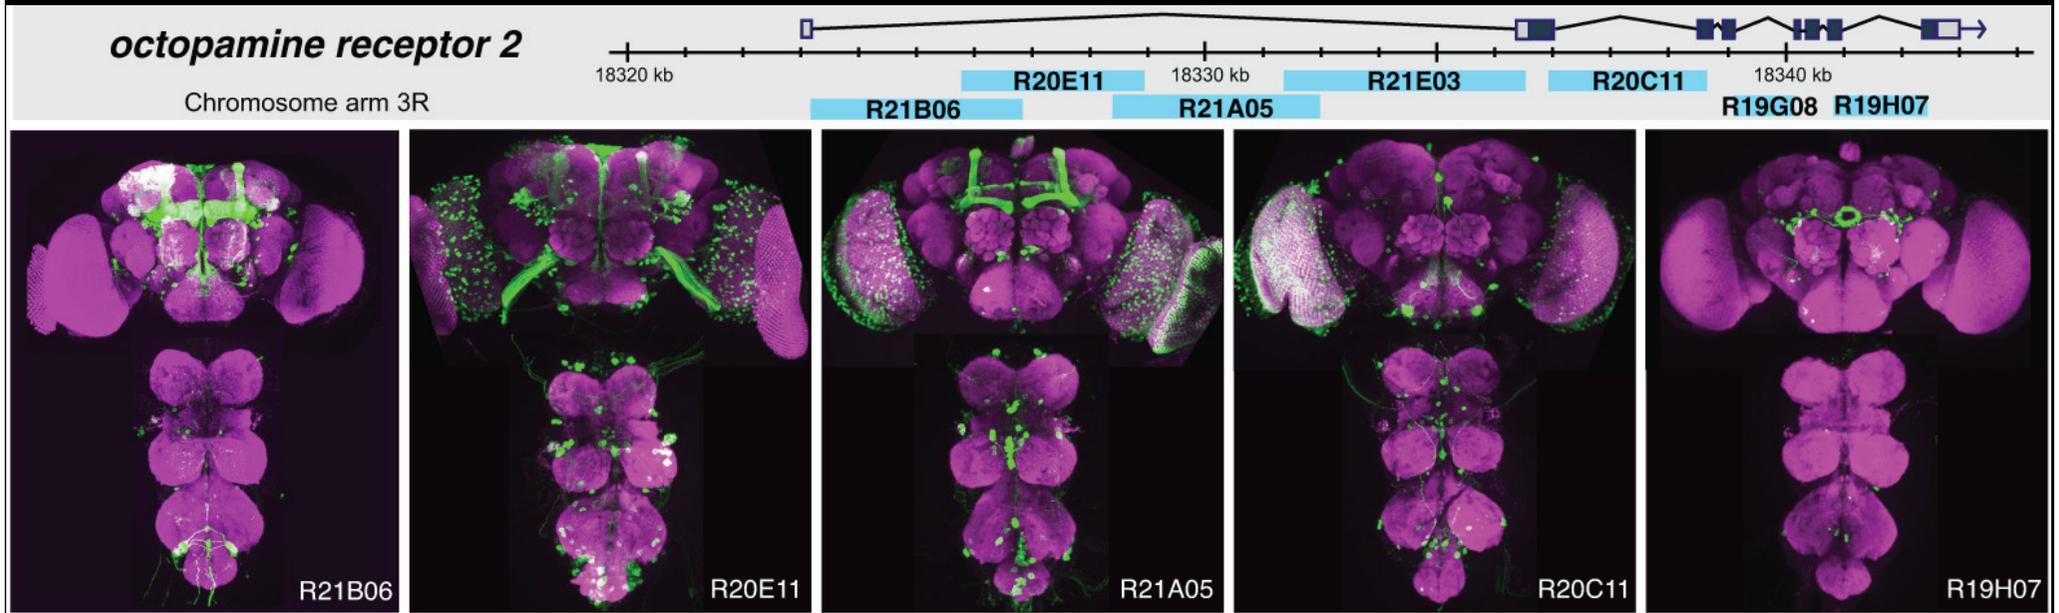

- * Can trace individual neurons but not collections thereof
- * Can register to 1.3 microns (average) reliably
- * The fly brain is highly stereotyped (1-2 micron variance)

Hierarchical Shotgun Mapping

Promotor: Sample 3Kbp promotor constructs to cover brain
Lines sparsely (8K). Select a covering set C (3K).

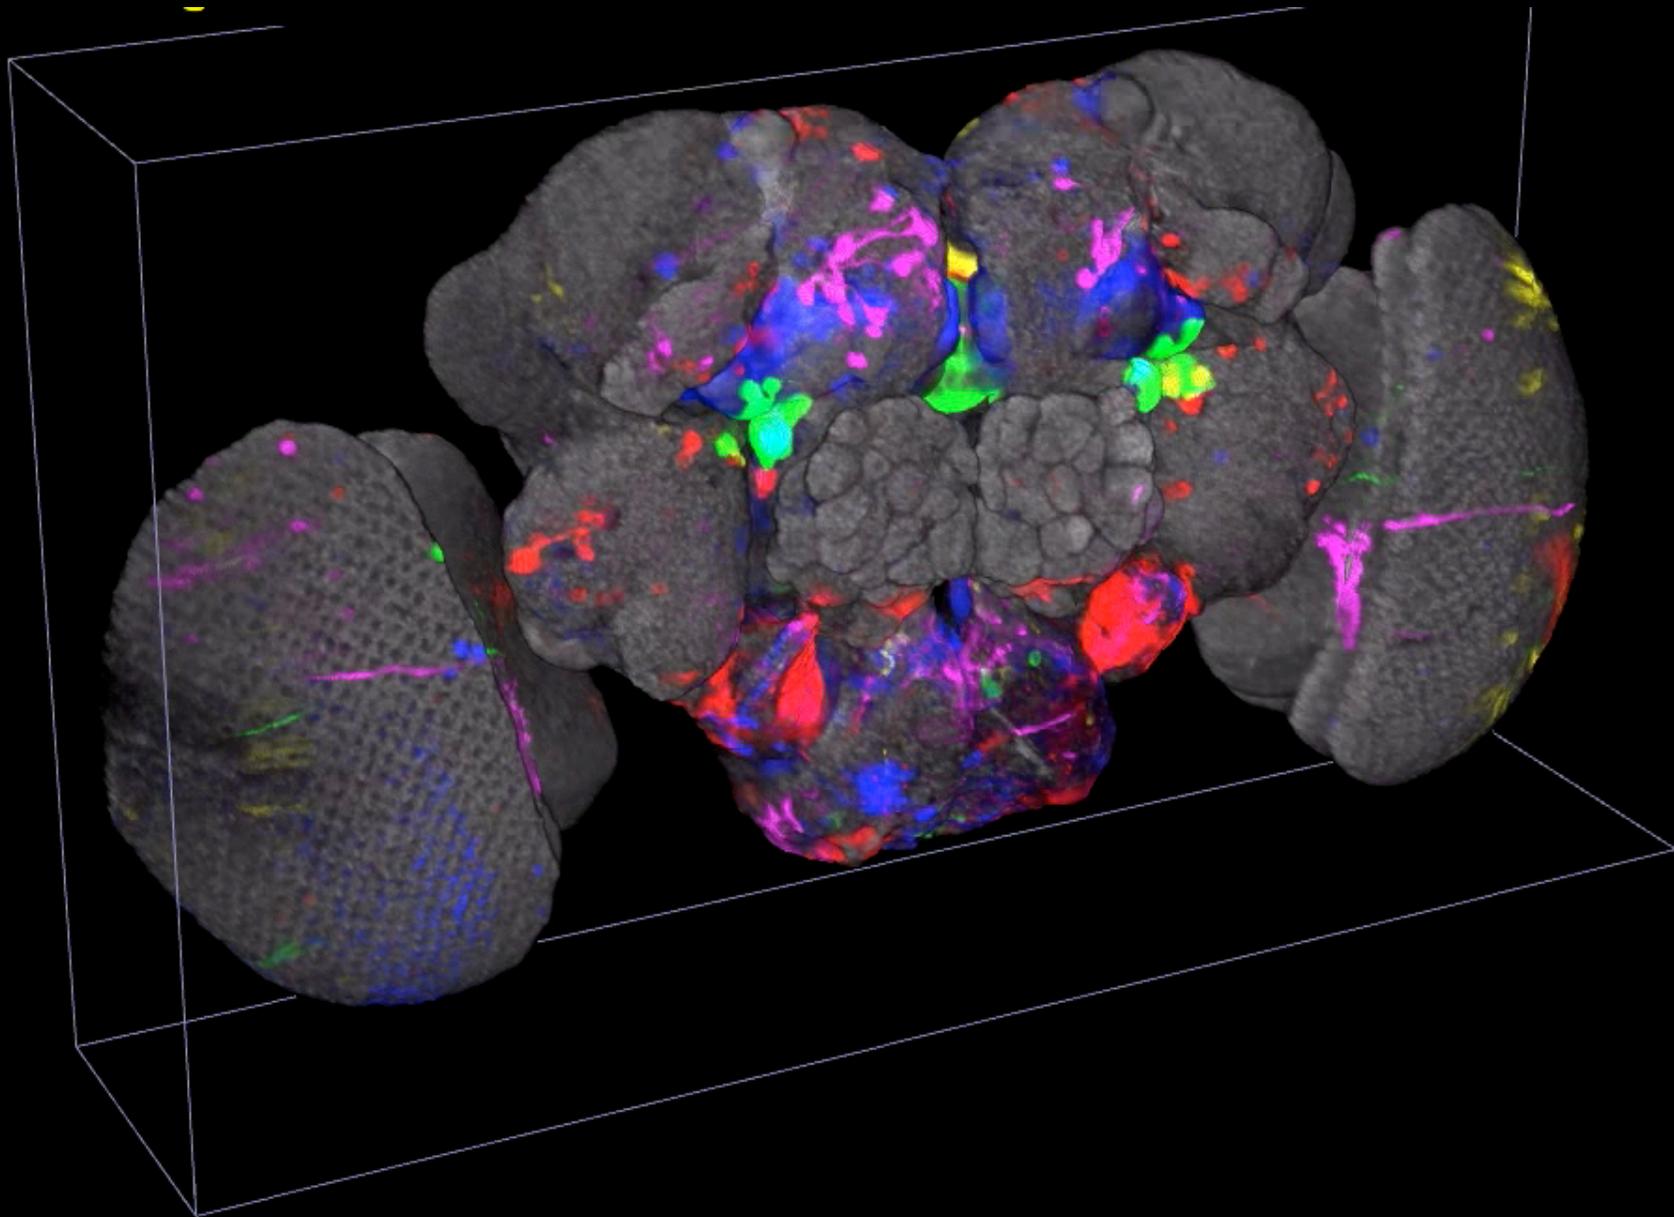

Examples of Promotor Assay

Pfeiffer *et al.* *PNAS* (2008)
Released Sept. 2012

Several Lines In "Atlas"

Anatomy of a Fly Brain *with Light*

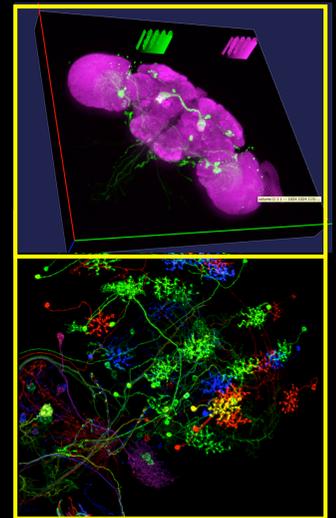

What we now know about image analysis for adult fly brain imaging:

Multi-Color Separation

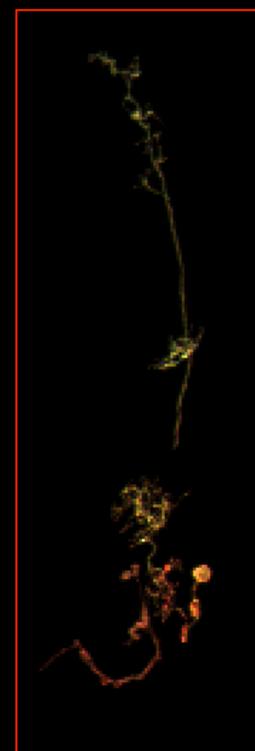

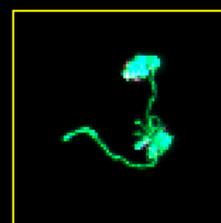

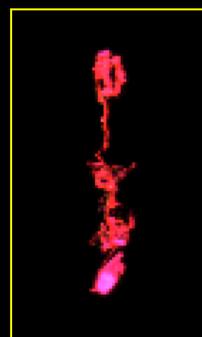

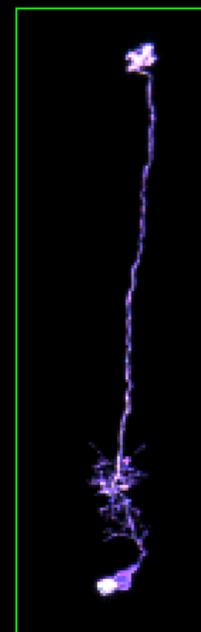

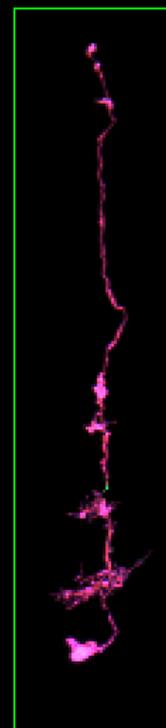

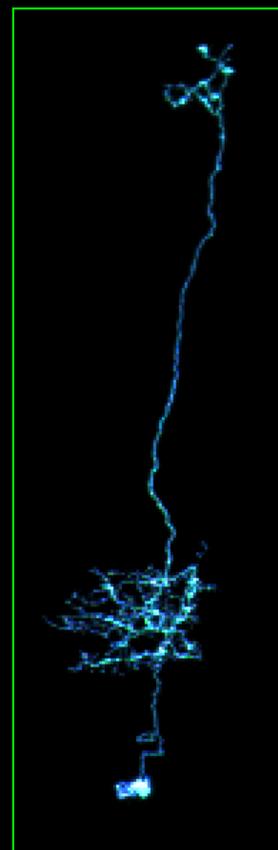

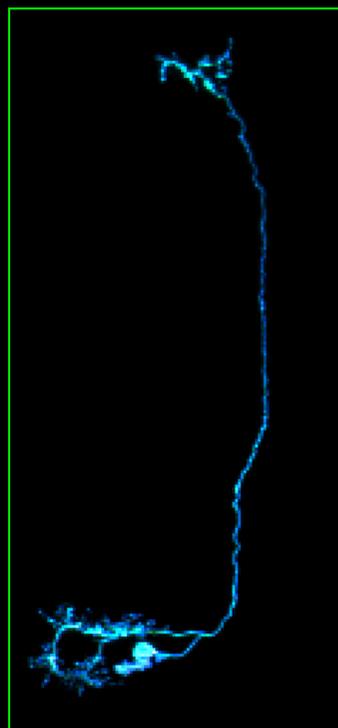

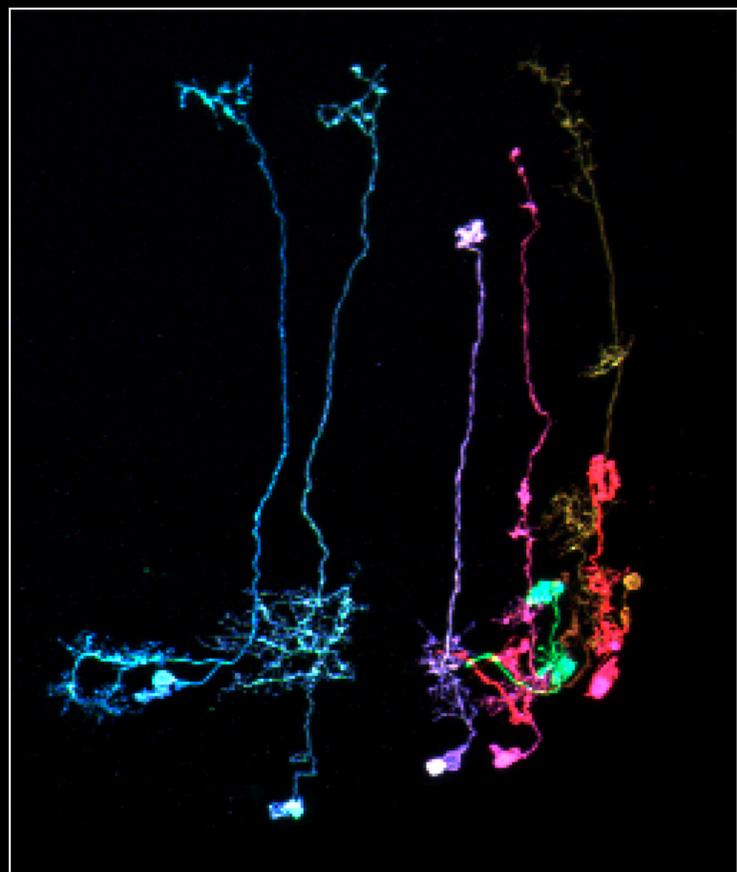

Color shift requires
sub-pixel translations!

Multi-Color Neuron Editing & Curation

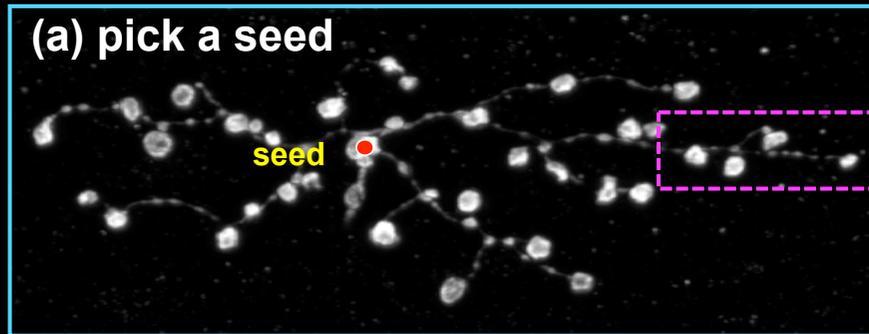

Neuron Tracing (w. H.Peng)

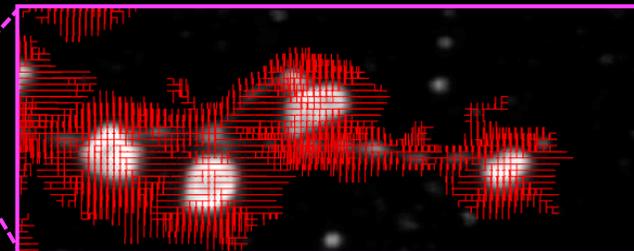

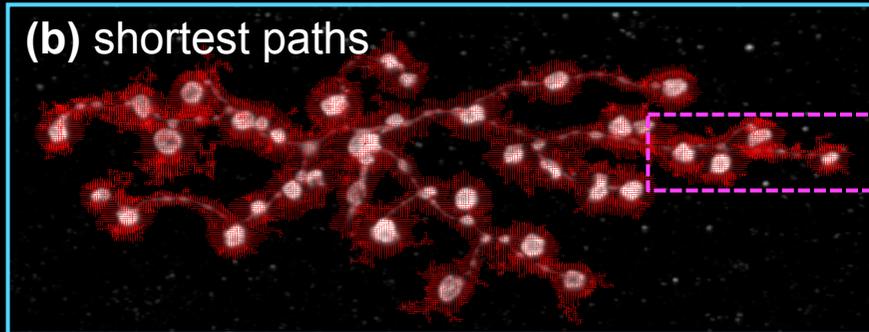

Bioinformatics 27 (2011)

(a) pick a seed

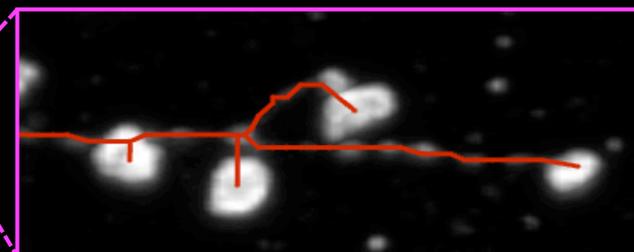

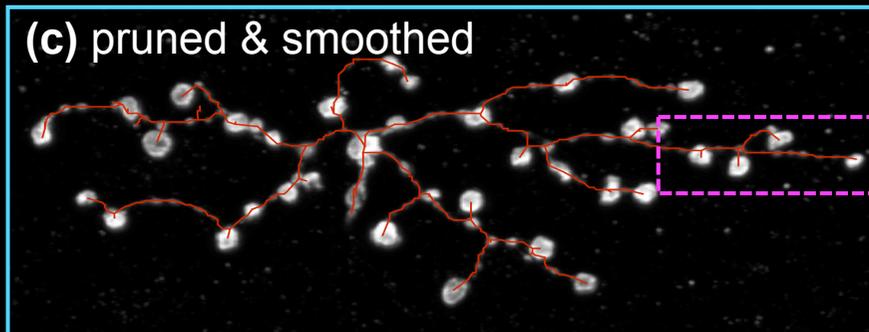

(b) shortest paths

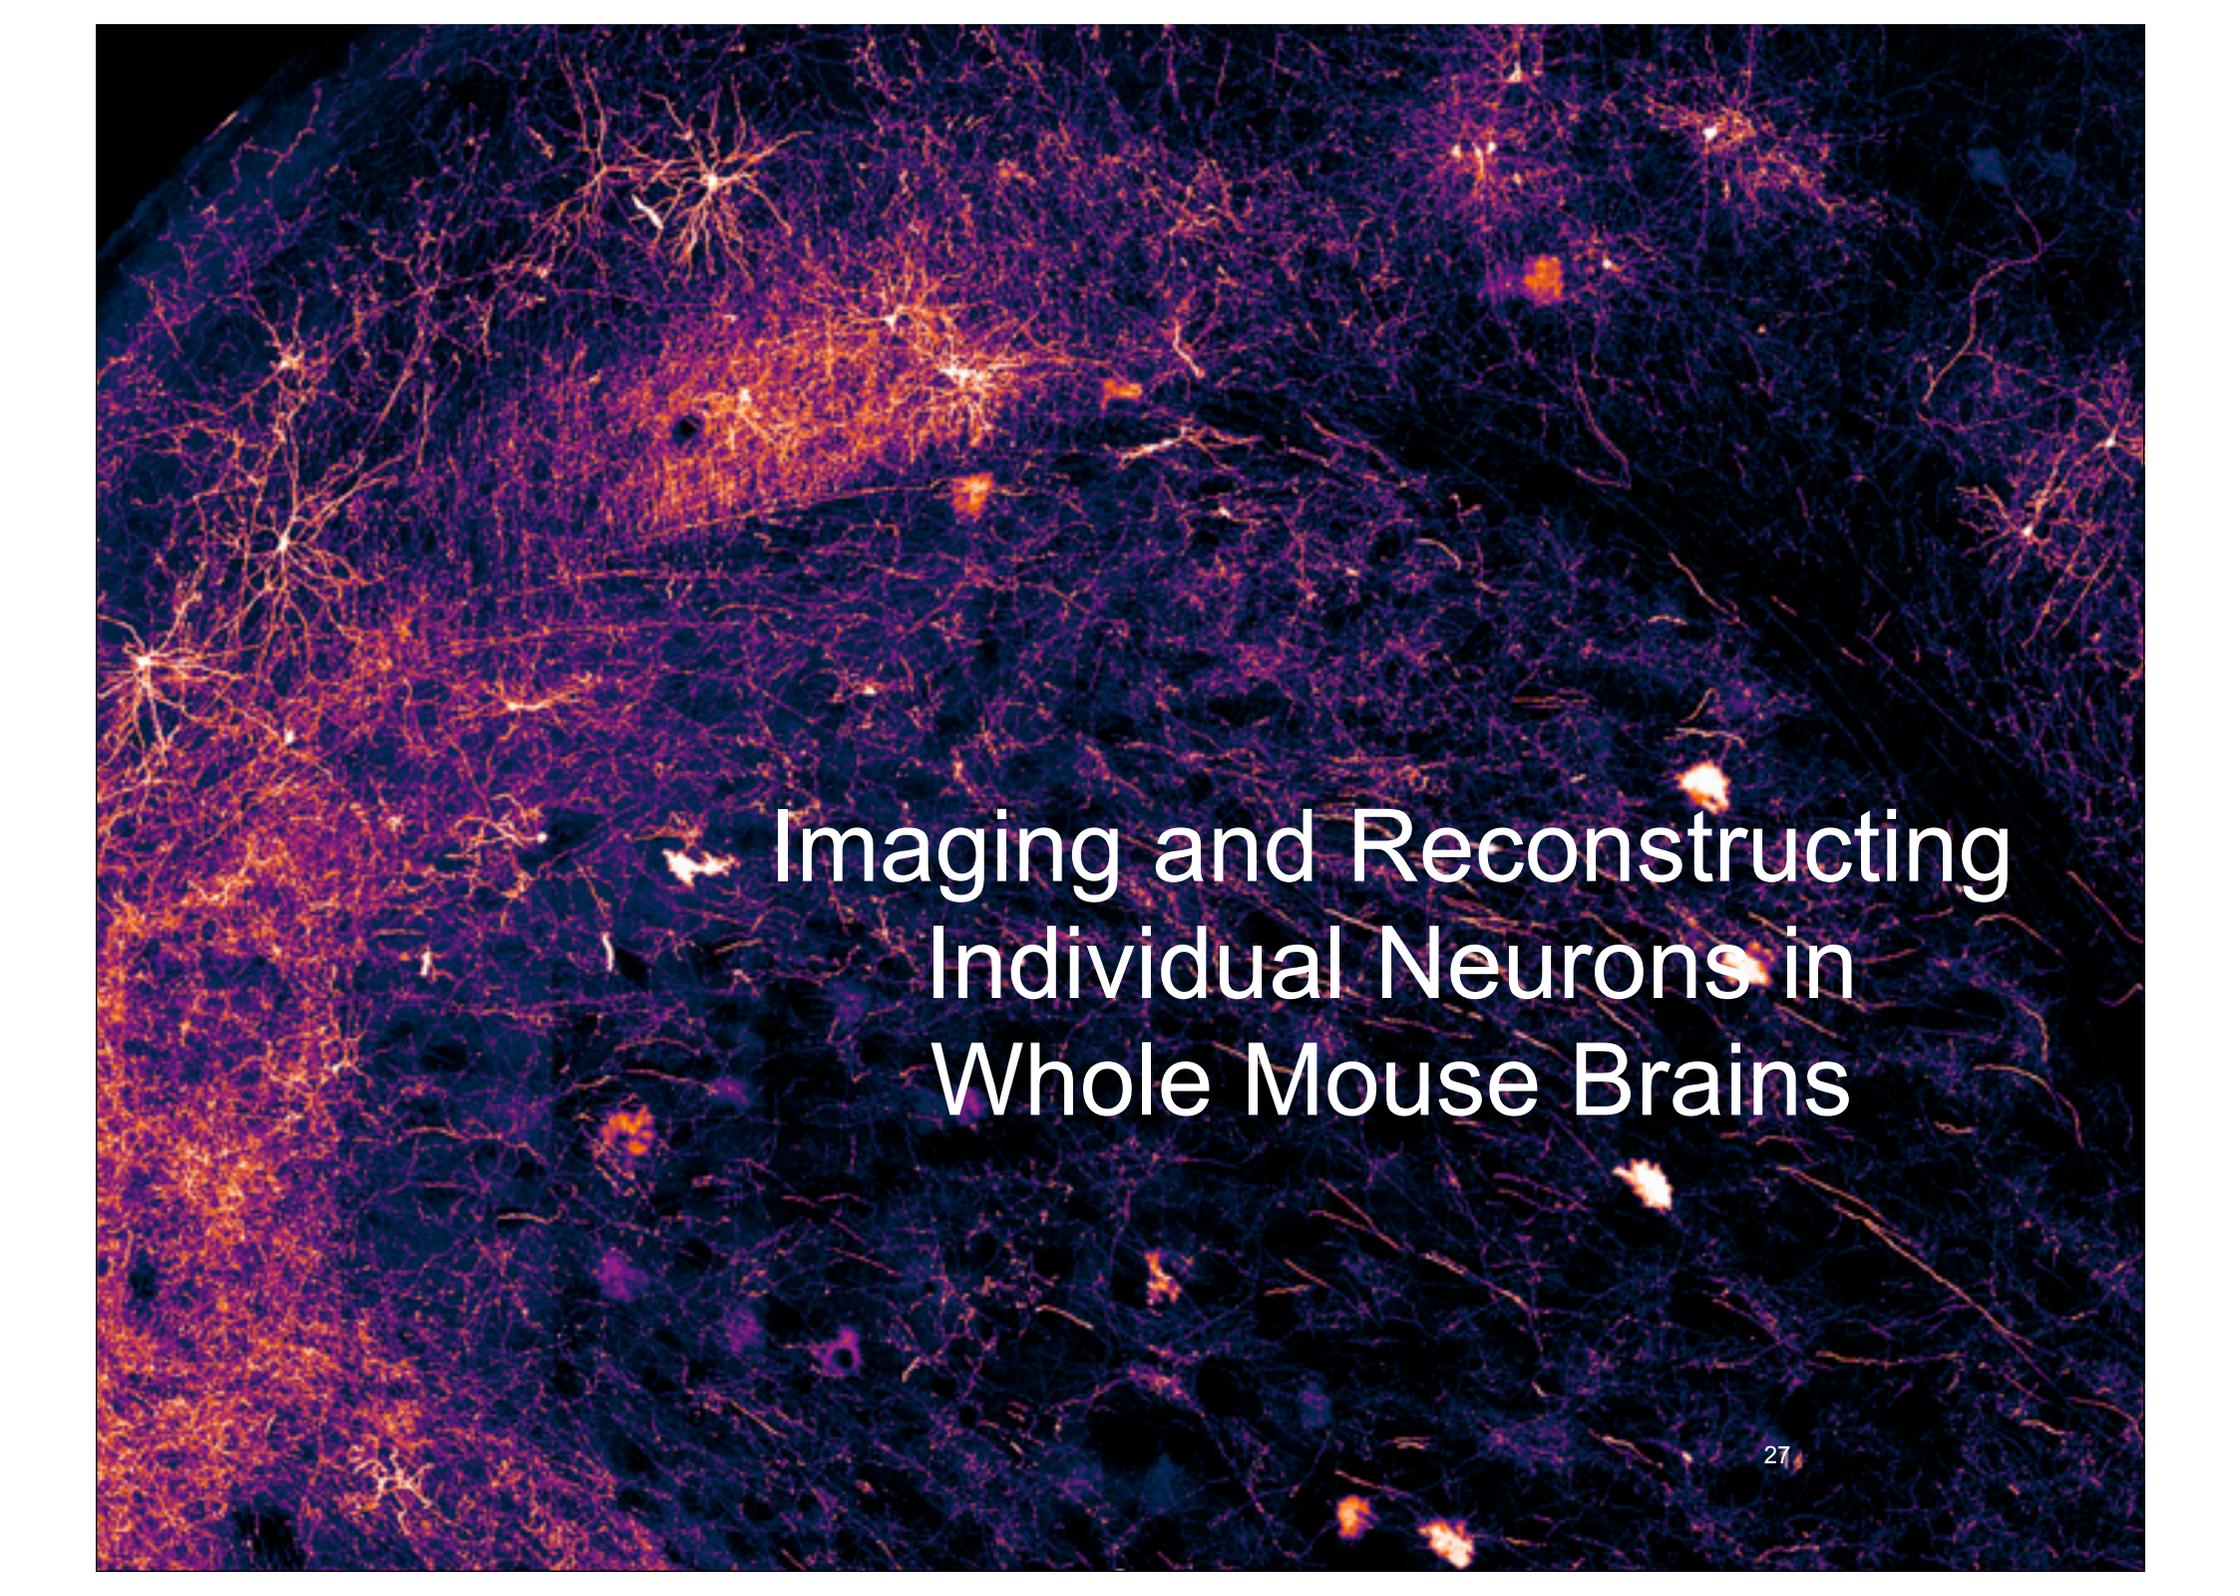

A discrete technique (from 1959), not typically used by CVers.

(c) pruned & smoothed

Another combinatorial idea. Each pixel covers a maximal disk of foreground, find minimum covering tree. Very fast, linear time.

Imaging and Reconstructing Individual Neurons in Whole Mouse Brains

The “Mouse Brain” Scope

Nathan Clack

Scale:

15 mm x 7 mm x 5 mm \Rightarrow 4.2×10^{12} $0.5^3 \mu\text{m}$ voxels!

Specs:

@ 8.6Mv/sec collect \sim 13,000 sub-stacks in $<$ 6 days
(86X faster than a conventional 2P scope)

Scope:

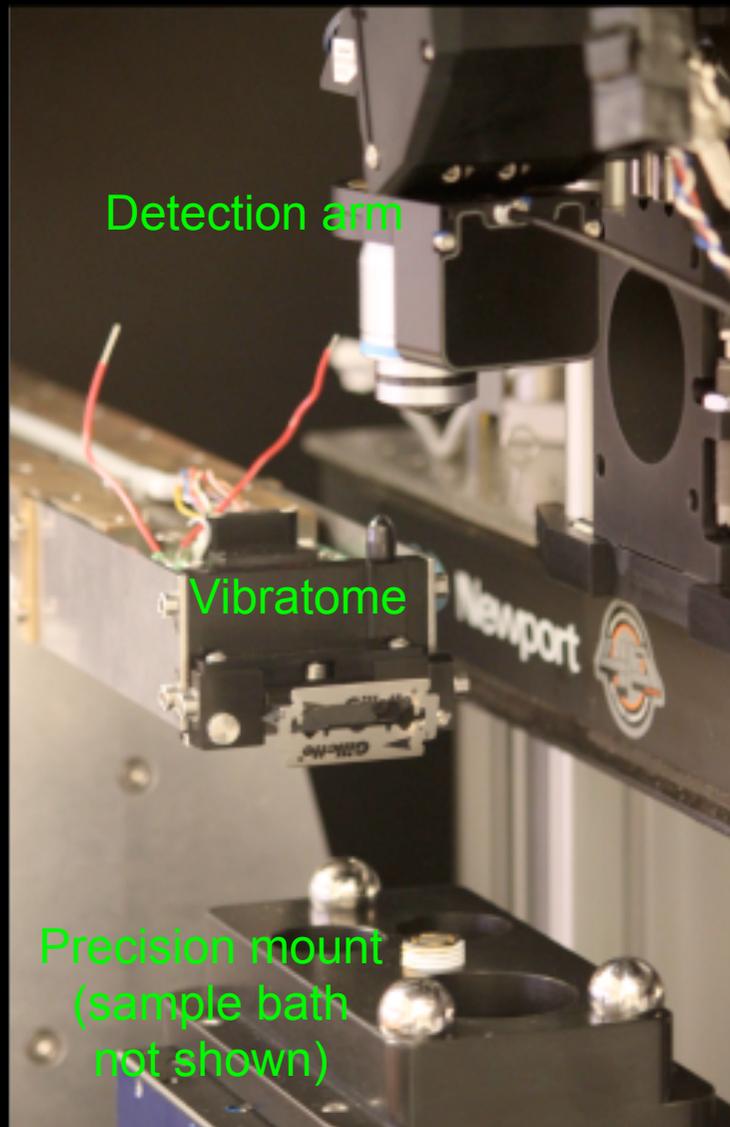

2P, block face, with on-board vibratome and resonant x-mirror automatically executing:

Repeat until nothing left

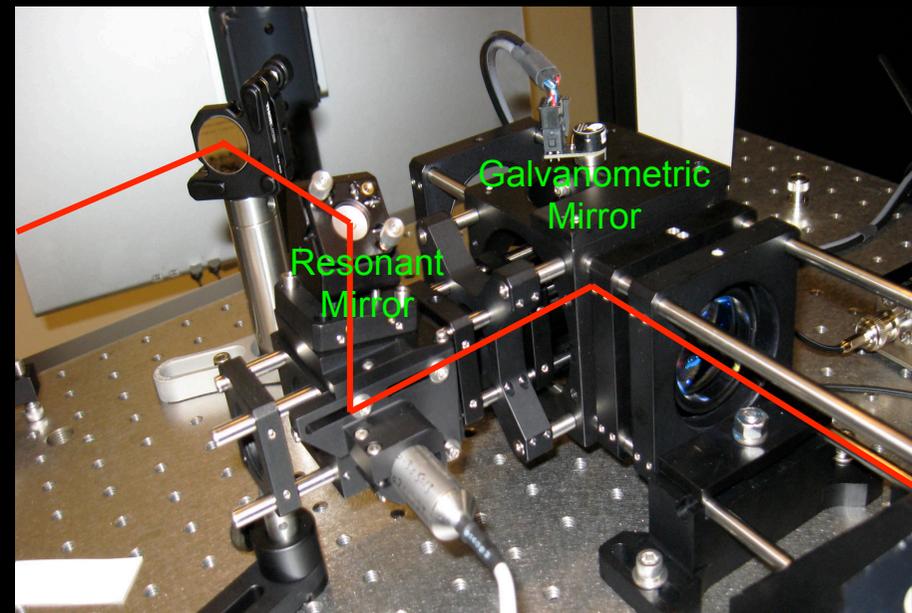

(1) Image an xy tiling of $200 \mu\text{m}$ deep stacks

(2) Cut away top $185 \mu\text{m}$ (implies $15 \mu\text{m}$ overlap)

Onboard Vibratome

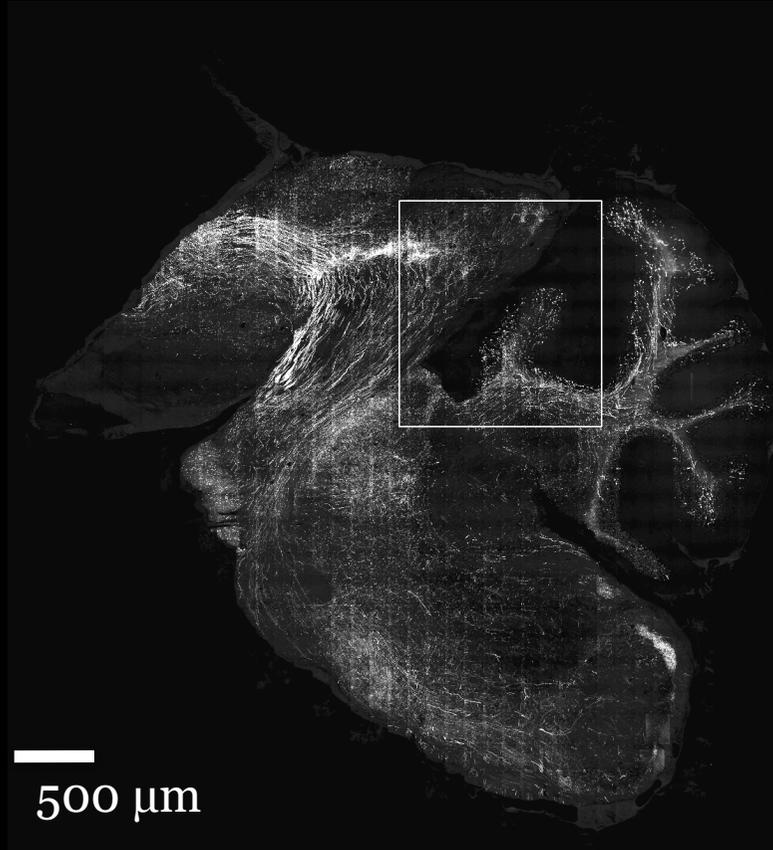

Resonant X-Mirror

30 μ m Sagittal Slice of Cerebellum (Hantman)

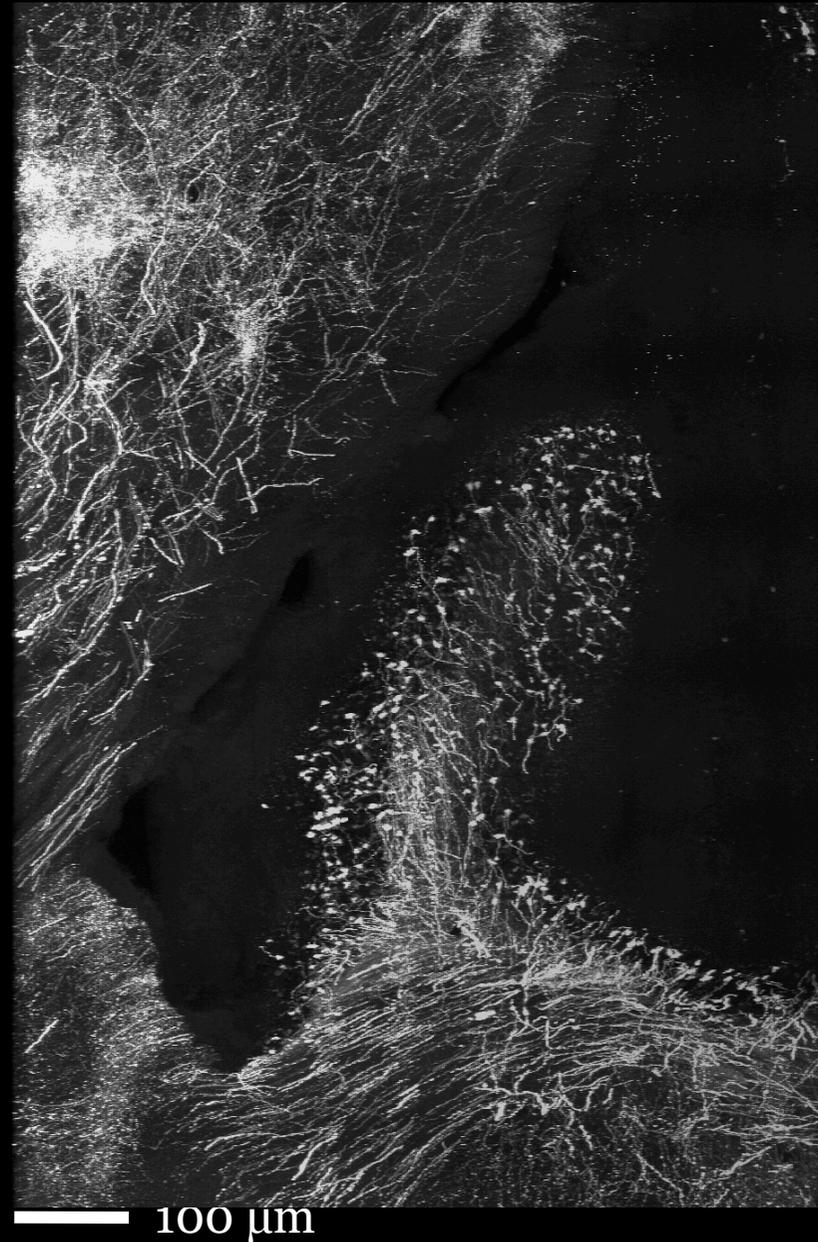

A small set of projecting axons from the central brain are labeled (GFP).

~1000 tiles

Voxel Size:
0.4 x 0.4 x 1 μ m

Acquisition Time: <1 hr.

Acquisition Software

Acquisition

Stage

Vibratome

Task control

The screenshot shows the 'fetch' software interface with several panels on the left and a large acquisition display on the right.

- Video Acquisition Panel:** Turn (px) 854.5, Y Lines (px) 512, Y Range (Vpp) 10, Pockels (mV) 0. Buttons: Attach, Arm, Run, Detach, Disarm, Stop.
- Stack Acquisition Panel:** Video Acquisition selected.
- Stage Panel:** X, Y, Z, Step. Pos (mm): 53.1090, 44.1600, 0.0000, 0.0500. Vel (mm/s): 2.0000, 1.0000, 10.0000, 1.0000. Not Moving, On Target. History: (0.9690, 0.9167, 0.0000) mm. Add button.
- Vibratome Panel:** Amplitude (0-255) 150, Feed distance (mm) 10, Feed velocity (mm/s) 1, Feed Axis Y, Cut Pos X (mm) 25.088, Cut Pos Y (mm) 78.08, Slice Thickness (µm) 50, Overlap Z (µm) 25. Buttons: Update stack depth, Update Z Overlap, Set Stage Step, Set cut origin, Move to cut origin, On, Off.
- Vibratome Geometry Panel:** Vibratome selected.
- Cut Cycle Panel:** Attach, Arm, Run, Detach, Disarm, Stop buttons.
- Tiling Panel:** Attach, Arm, Run, Detach, Disarm, Stop buttons.

The main display area is a 'Tiling editor Acquisition display' showing a grid of yellow squares forming a circular pattern. A blue arrow points to one of the squares with the text 'Each square is a single stack'. A scale bar at the bottom right indicates '1 cm'. The status bar at the bottom shows 'FileSeries: H:\ 2011-11-21\ 00001\ ' and 'Config: C:/Users/clackn/Desktop/test2.microscope'.

Mol. Reagents

Developmental
& Cell Biology

Bioimage
Informatics

BioPhysics
& “Sys. Bio.”

(a) Meso-scale interpretation & simulation of cellular phenomenon

(b) Platform to (perfectly) follow cell lineages through arcs of time
(e.g. worms, fly embryos, fly wing development, z.fish embryos)

(c) Connecting (a) & (b)

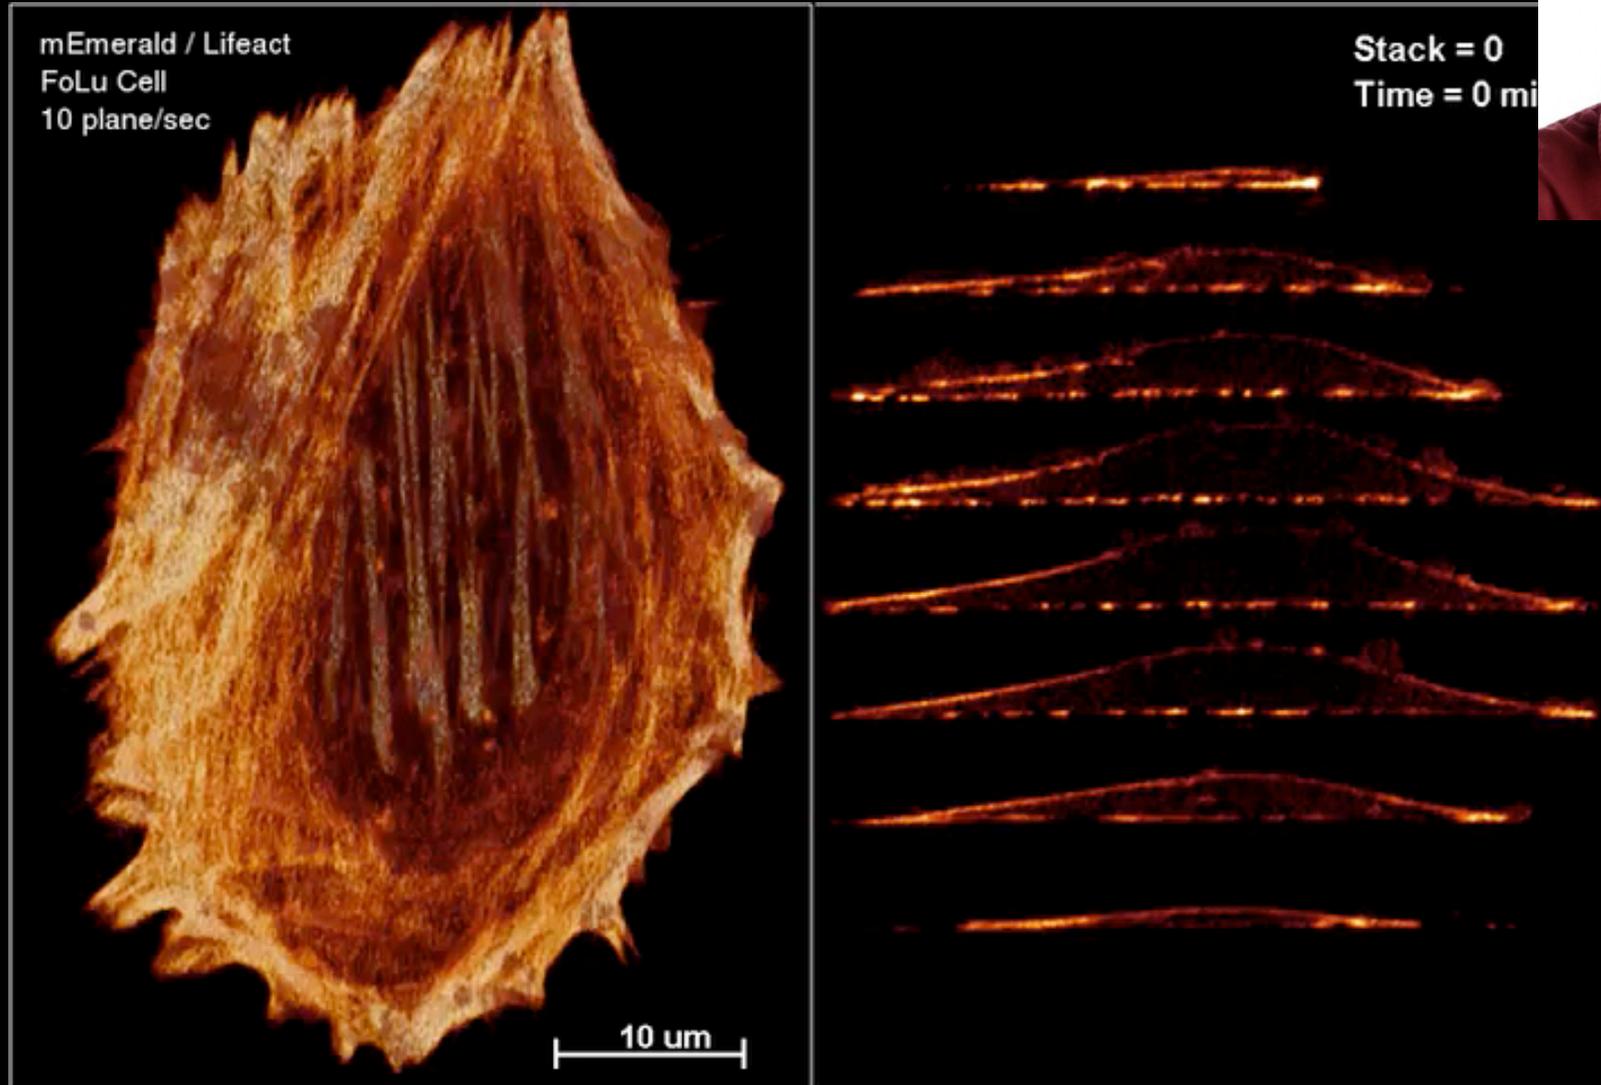

We will:

- build (automated) microscopes,
- design algorithms for extracting information and models from images, and
- build computer-assisted interfaces for curation and analysis.

Tracking Lineages During Fly Embryogenesis

- 96 time points; 35secs/time point (TP)
- ~4800-9600 cells/TP
- CPU+GPU: 110 secs/TP

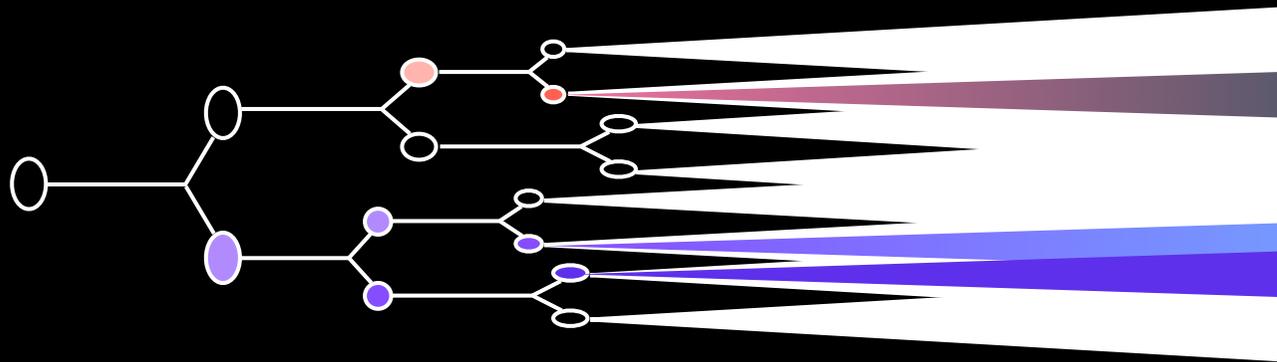

Fernando Amat

01:03:00

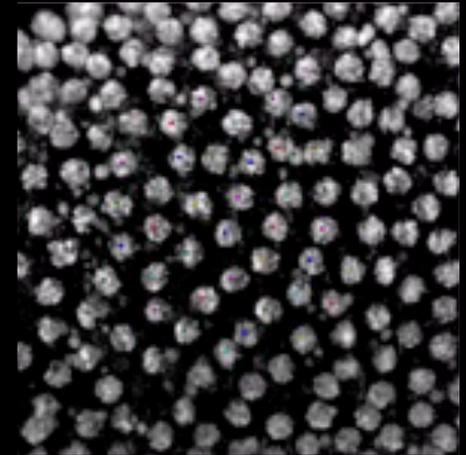

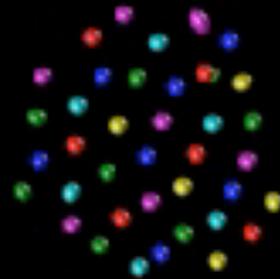

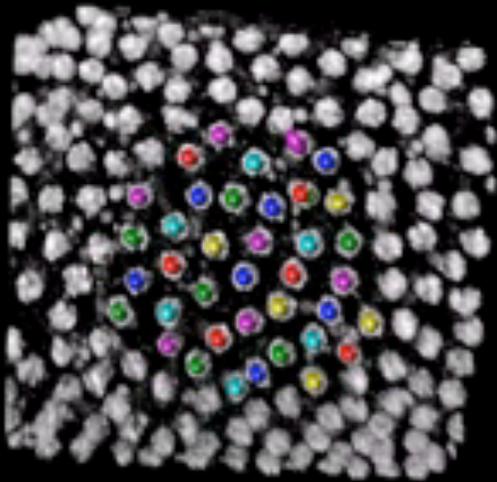

Tracking Lineages During Fly Embryogenesis

- Lineage tree with arc-lengths, $\text{shape}(t)$, and $\text{expression}(t)$ of 1 or more agents.

- If can attain this goal then can go from developed structures backward in time to founder cells, and
- Can throw away Tb's of "raw data". The "lineage" can be encoded in a few Mb's.

Tracking Detail View

- Segmentation accuracy: $96.7\% \pm 1.0\%$
- Simple linkage accuracy: $99.2\% \pm 0.6\%$
- Cell division linkage accuracy*: $94.8\% \pm 2.6\%$
- Error-free lineages (approx): 74.5% (1502 trees)

How Hard is the Problem?

- At 99.9% tracking step accuracy and 2,880 steps (1 stack/30 sec.s), 5.6% of lineages will be correct.
At 99.99%, 75%.
At 99.999%, 97%.
- We need better scopes (even 50% more rez will help), we need software that is 3 orders of magnitude more accurate than current solutions.
- We will always need to curate, so need computer-assisted GUI's that make that as efficient as possible.

So

I believe that direct *in-vivo* and *in-situ* observations of cells and cellular systems is going to lead to the most exciting and meaningful discoveries in molecular biology in the next decade. This belief is founded on two facts.

1. We can now label any protein, RNA, or other genetic element of interest within a model organism as we now have their DNA sequences.
2. Advances in microscopy enable us to view these labeled agents with greater fidelity, speed, and duration than ever before.
